

Transfusion Support for Sickle Cell Disease

Jacob Pendergrast, MD, FRCPC
University Health Network Blood Transfusion Service
Assistant Professor, University of Toronto

DISCLOSURES

- ▶ None

Objectives

1. Outline the principles of RBC transfusion in sickle cell disease
2. Define accepted indications for RBC transfusion in sickle cell disease
3. Recognize the syndrome of hyperhemolysis and the importance of careful RBC selection in preventing it

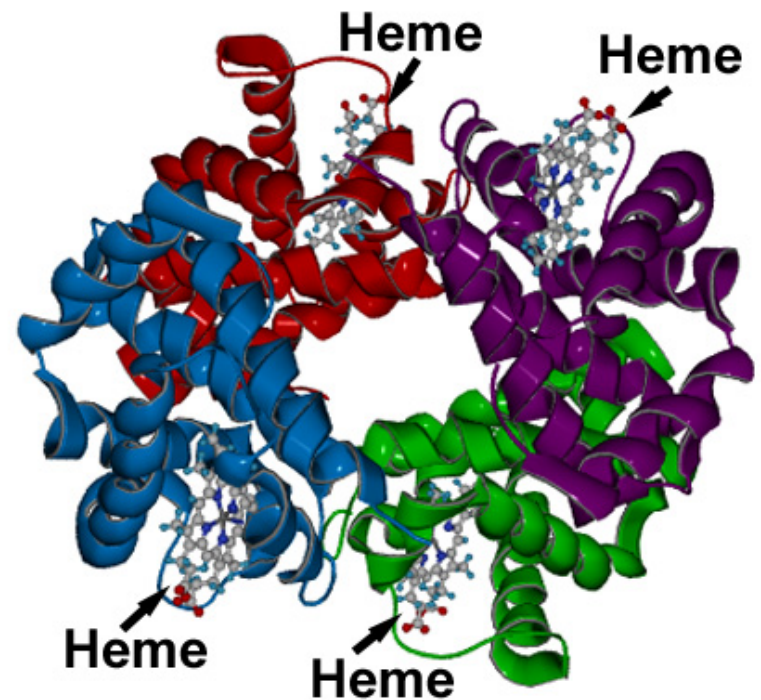

What is Sickle Cell Disease?

Hemoglobin: An Overview

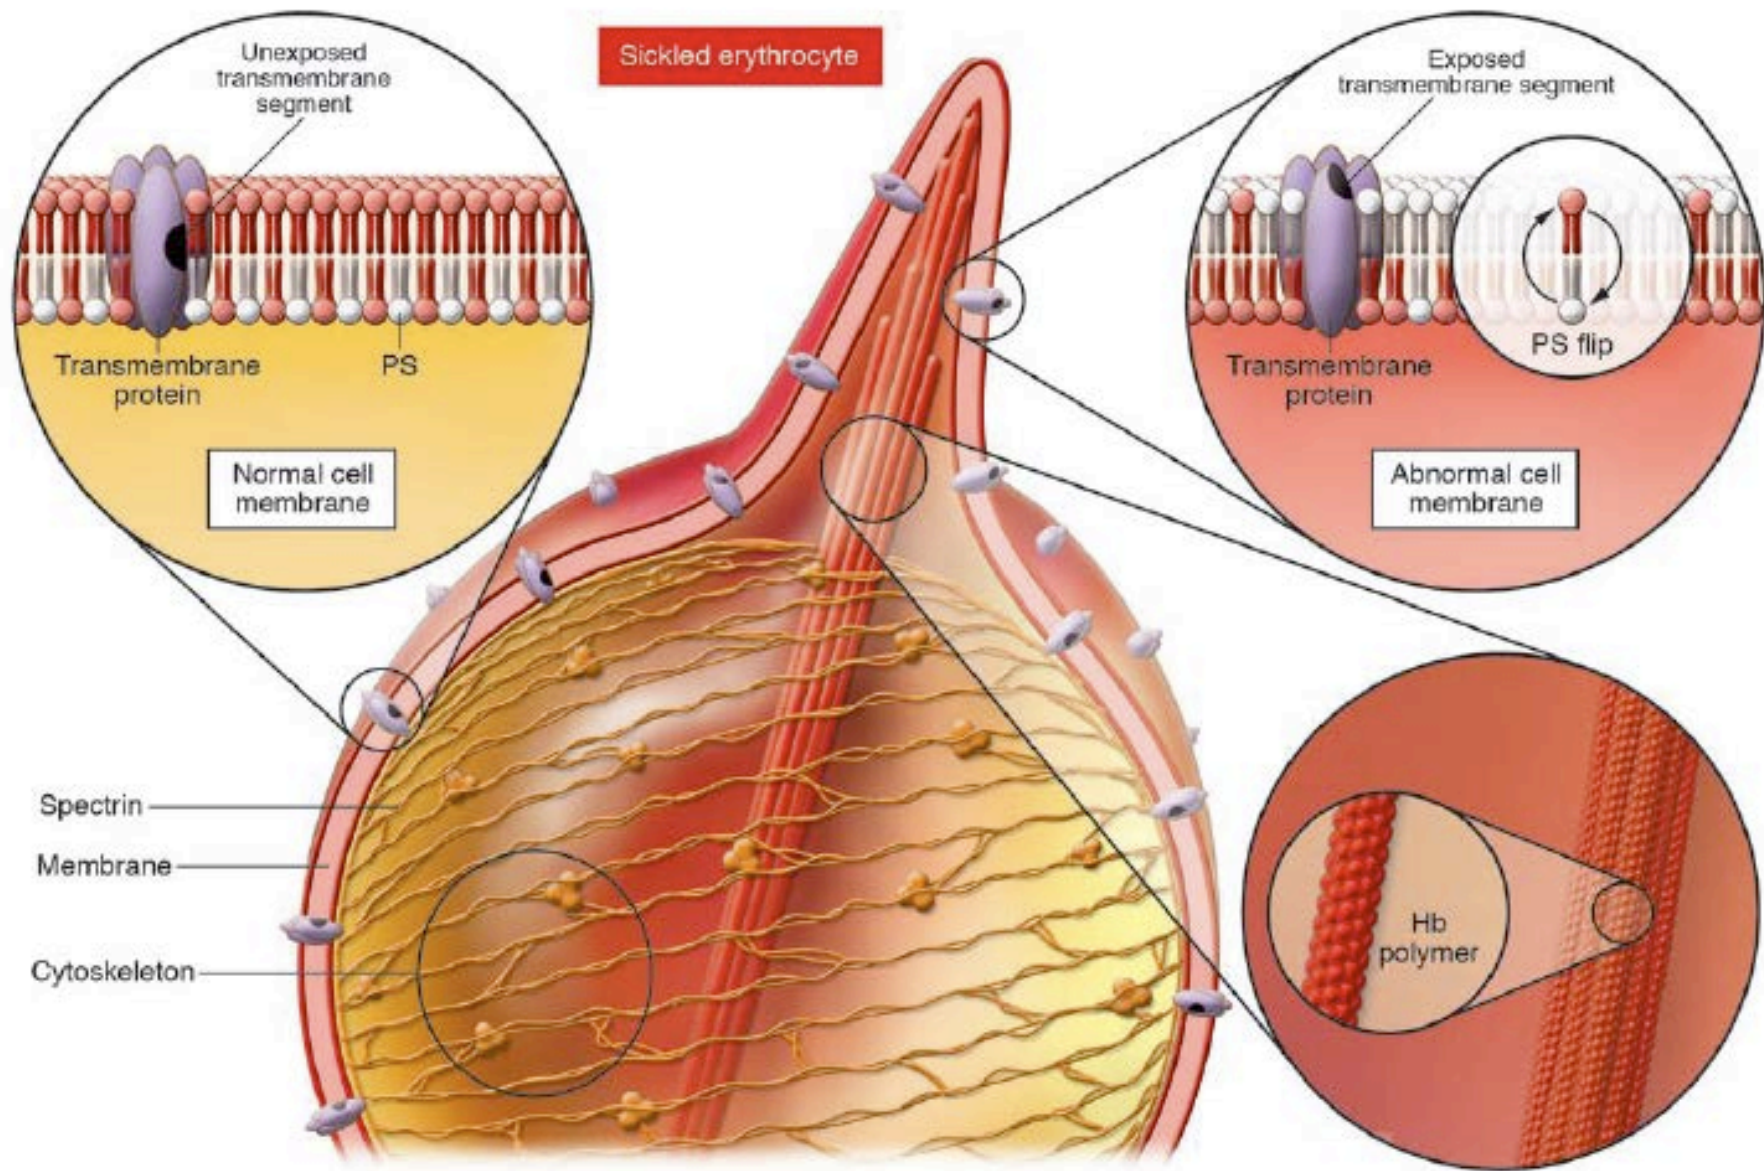

- ▶ **Structure of hemoglobin**
 - ▶ 4 globin chains (2 x alpha and 2 x beta), each containing a heme group within a protected pocket
 - ▶ When deoxygenated, Hgb in “taut” configuration, beta globin chains held apart with ionic bonds
 - ▶ With oxygen binding, ionic bonds broken, beta globin chains move together and Hgb adopts “relaxed” configuration

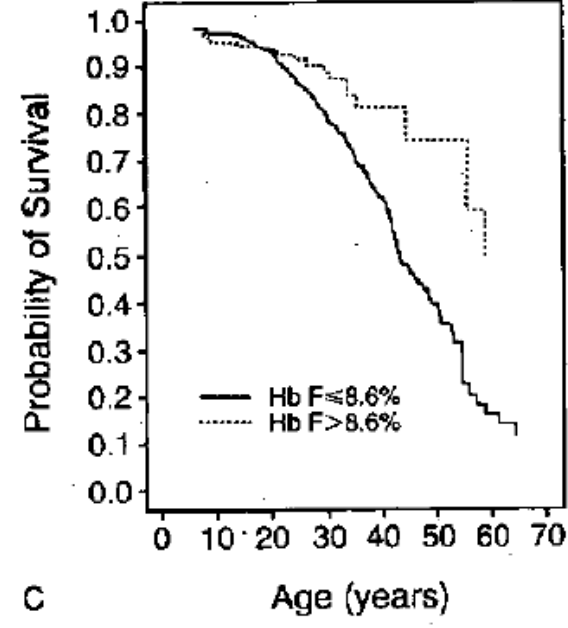

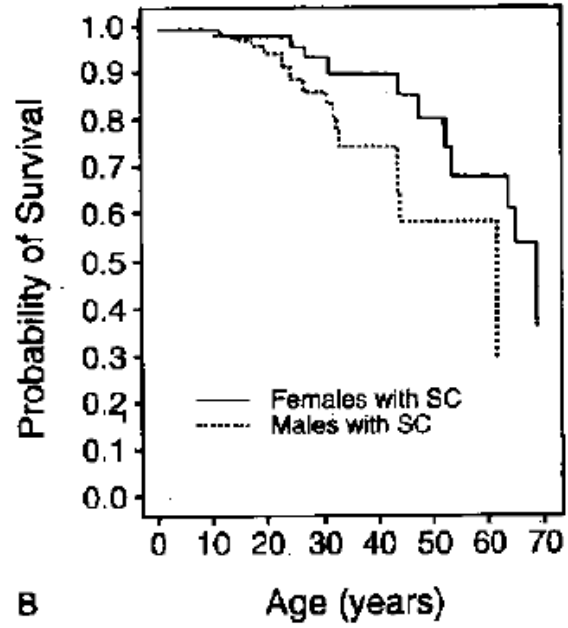

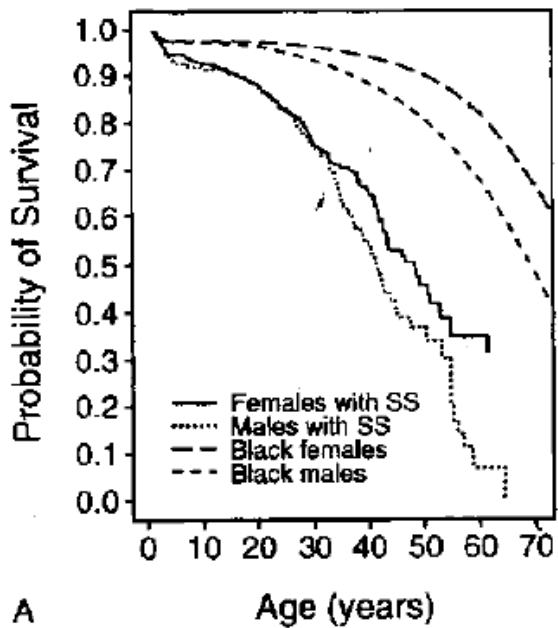

Sickle Cell Disease: Pathophysiology

- ▶ Due to specific point mutation in sixth codon of β -globin gene
- ▶ Resulting HgbS has a hydrophobic domain which predisposes to precipitation when deoxygenated
- ▶ HgbS polymerization results in formation of elongated fibres which stretch and deform the erythrocyte
- ▶ Membrane damage results in cellular dehydration, rigidity, adhesiveness/thrombogenicity
- ▶ Net result: hemolysis, vaso-occlusion

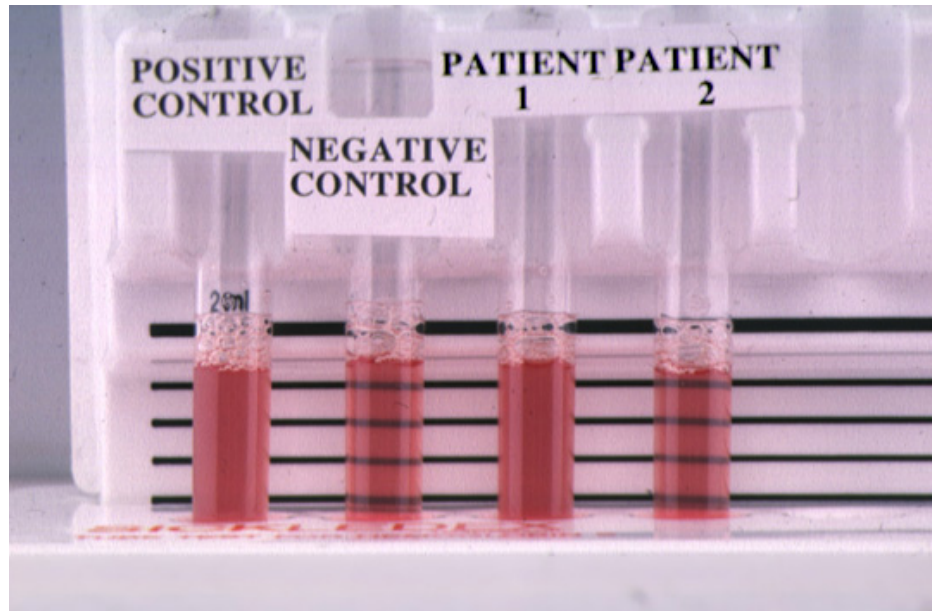

Genotype	HgbS	Typical clinical severity
β^S/β^A	HgbS: 20-30%	Asymptomatic
β^S/β^C	HgbS: 50%	Mild-moderate
β^S/β^+	HgbS: 70-85%	Moderate
$\beta^S/\beta^0, \beta^S/\beta^S$	HgbS: 90-95%	Severe

A note on screening

- ▶ After 6 months age, sickle cell solubility testing (Sicklelex®) will detect all sickling syndromes (HgbSS, Sβ, SC, etc) AND HgbAS (sickle cell trait)
- ▶ Patients with a positive solubility test must undergo confirmatory testing by hemoglobin electrophoresis/high-performance liquid chromatography

A note on screening

- ▶ Is it necessary to screen at-risk ethnicities (African, Greek, Southern Italian, Turk, Arab, Indian) for sickle cell disease prior to surgery?
- ▶ Consider the following:
 - ▶ >95% of patients will have already manifested clinically by age 10
 - ▶ Universal newborn screening in place in Ontario since 2006
 - ▶ Diagnosing sickle trait (50x more common than sickle cell disease) pre-operatively may create needless delays in care
- ▶ **Careful history and physical/early referral to hematology of known SSD cases probably much more important than routine pre-operative lab screening**

Which homozygote sickle cell disease patient warrants an exchange transfusion?

28 year old female G1P0, 25 weeks pregnant with Hgb 70g/L

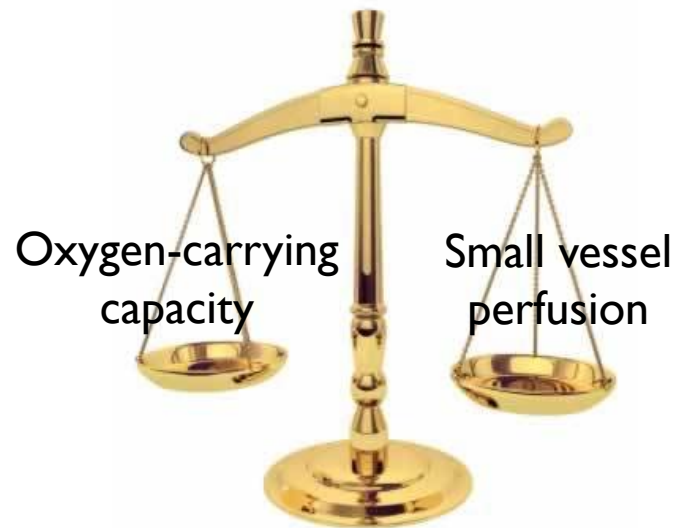

45 year old woman with Hgb 34g/L with an aplastic crisis

21 year old female with vaso-occlusive crisis and Hgb 70g/L

20 month old girl going for cholecystectomy with Hgb 80g/L

38 year old female with acute chest syndrome requiring mechanical ventilation

Oxygen Delivery: A Balancing Act

Oxygen Delivery

MACROCIRCULATION

Oxygen Delivery = Cardiac Output x Oxygen Carrying Capacity of Blood

$$DO_2 = CO \times CaO_2$$

Predominantly determined by Hgb

Higher Hgb = More Oxygen Delivery

MICROCIRCULATION

$$\text{Flow} = \frac{\text{pressure} \times \text{radius}^4 \times \pi}{8 \times \text{tube length} \times \text{viscosity}}$$

$$v = \frac{P \times r^4 \times \pi}{8 \times l \times \eta}$$

Predominantly determined by hematocrit

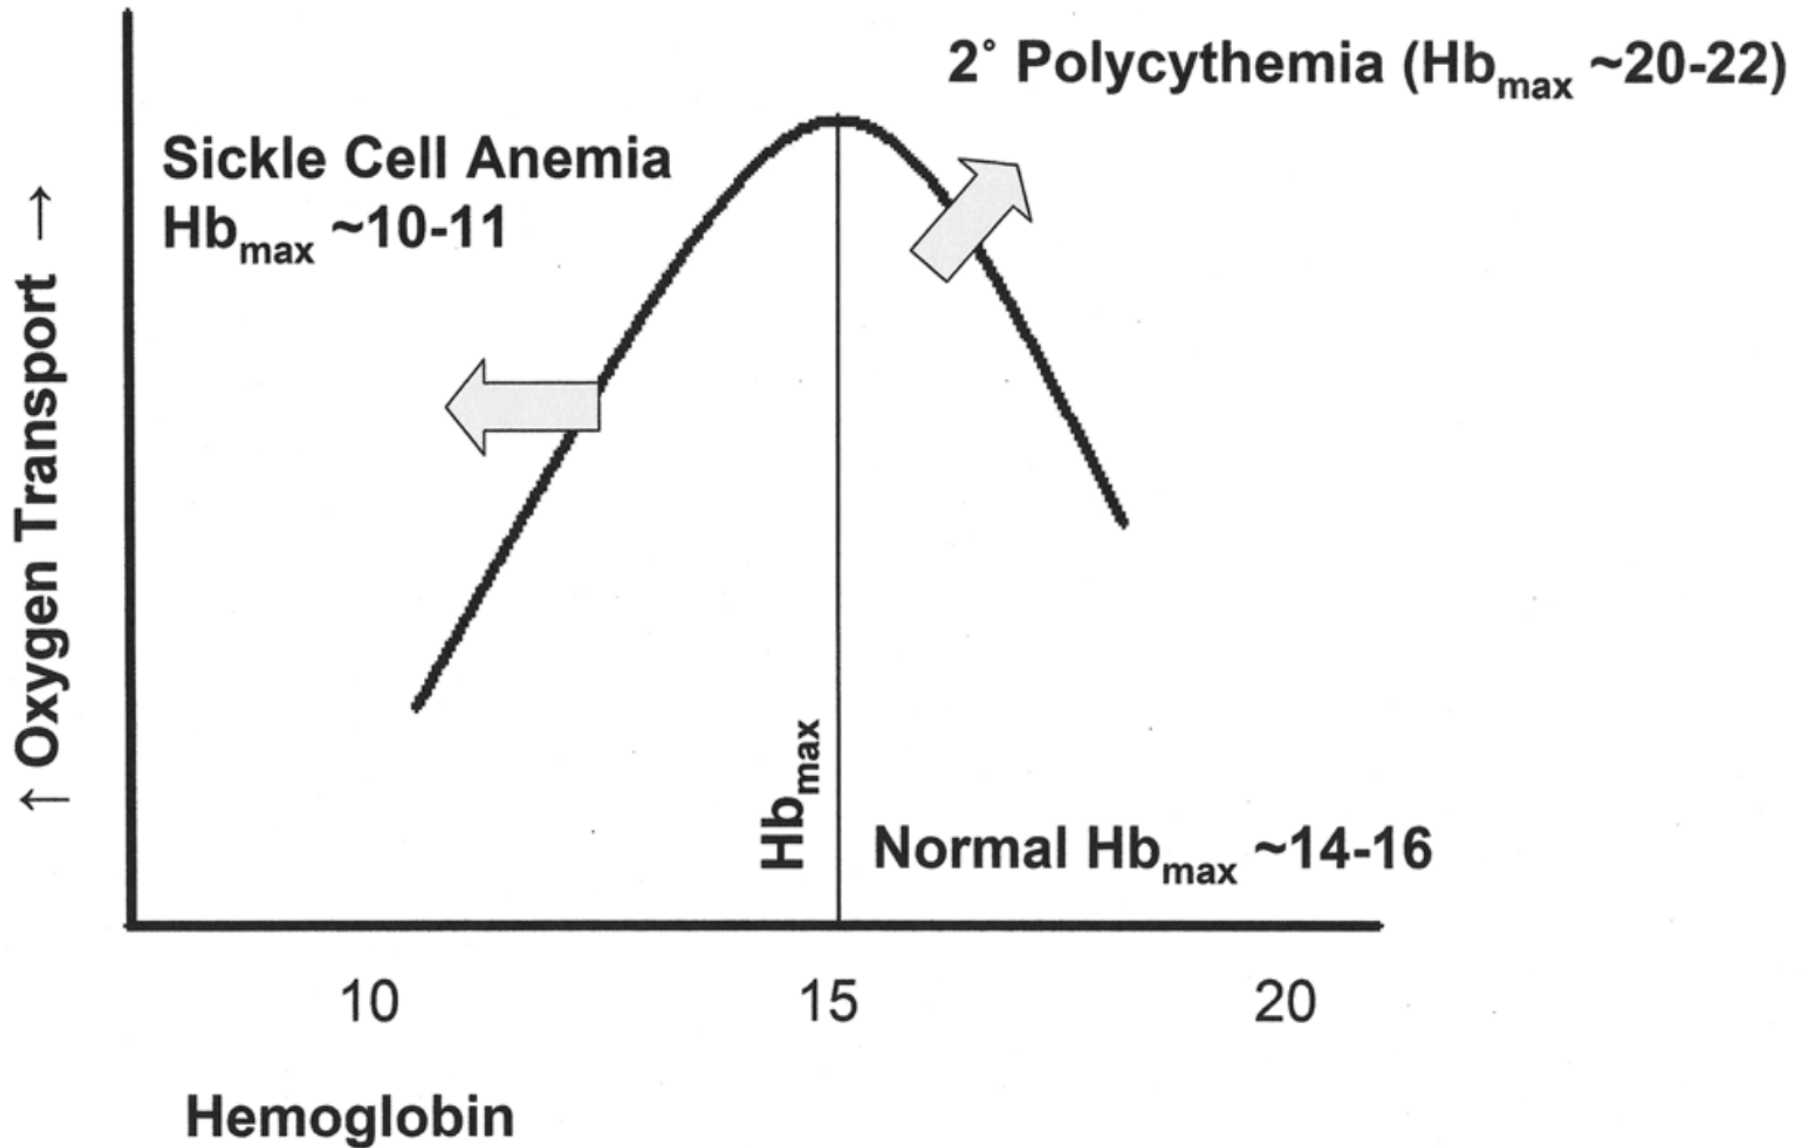

Lower flow = lower oxygen delivery

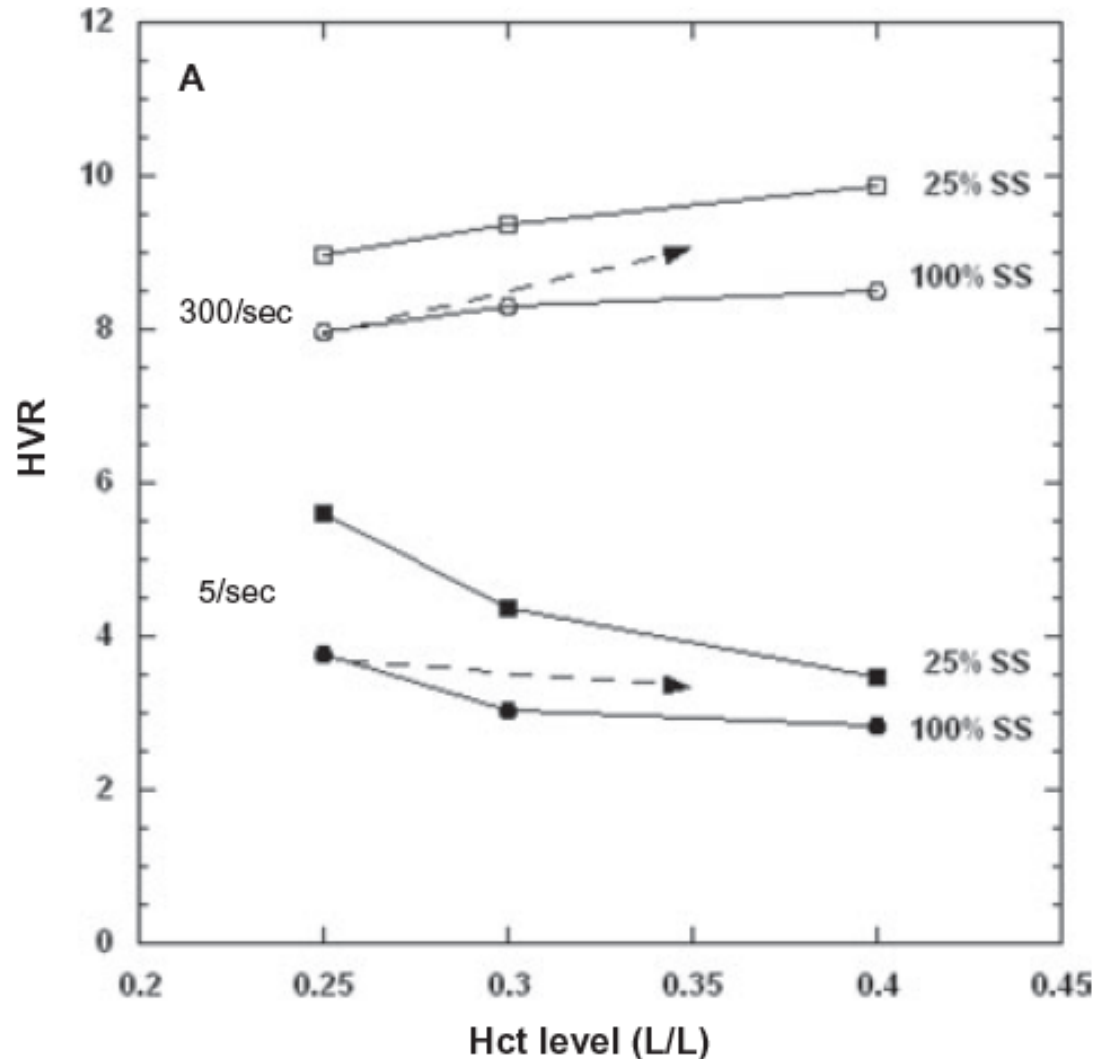

Higher Hgb = Less Oxygen Delivery

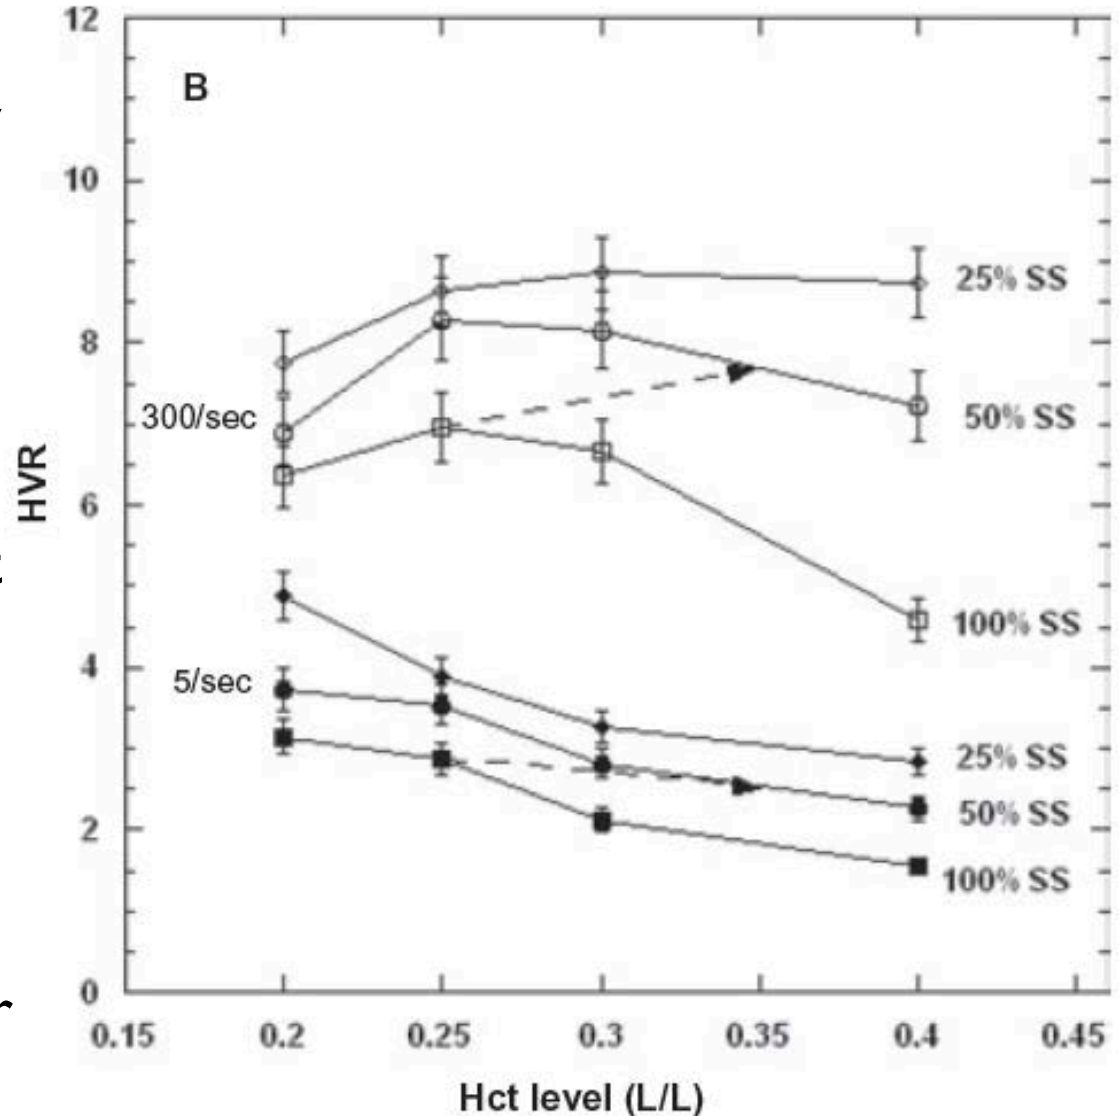

Hematocrit:Viscosity Ratio vs Hct for **Oxygenated** Sickle Cell RBCs

- ▶ At high shear blood flow, viscosity increases at a slower rate than Hct over wide-range of Hct values, whether HgbS is 100% or 25%
- ▶ At low shear, however, increased RBC:protein interactions exacerbate viscosity, which therefore increases faster than Hct

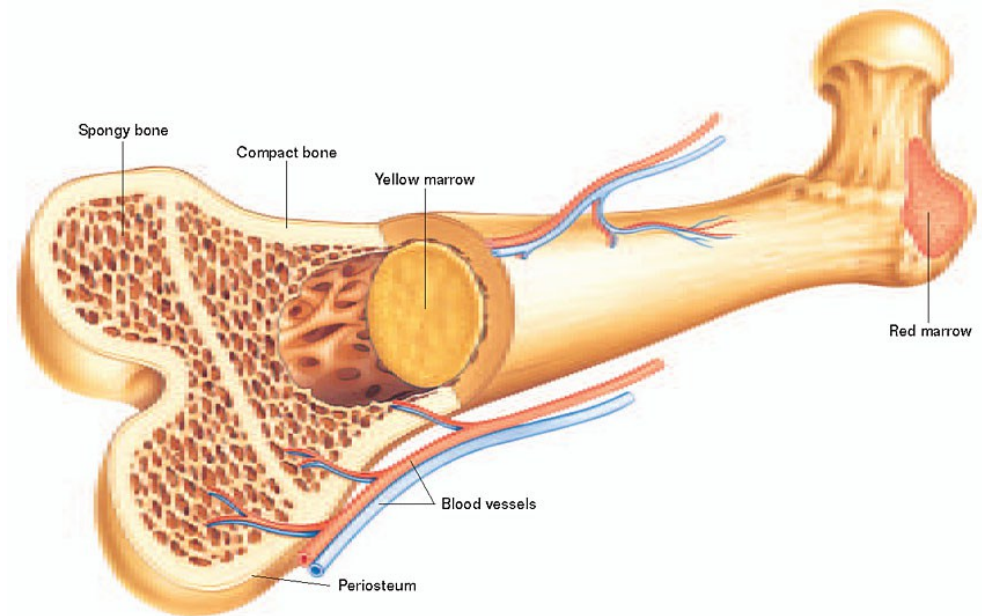

Hematocrit:Viscosity Ratio vs Hct for **Deoxygenated** Sickle Cell RBCs

- ▶ While oxygenated sickle blood is already more viscous than normal blood, the viscosity increases dramatically when deoxygenated
- ▶ Result is an apparent optimal Hct of 25% at high shear, even if HgbS diluted to 25%, no further benefit in increasing Hct past 30%
- ▶ Even lower Hct may be better at low shear

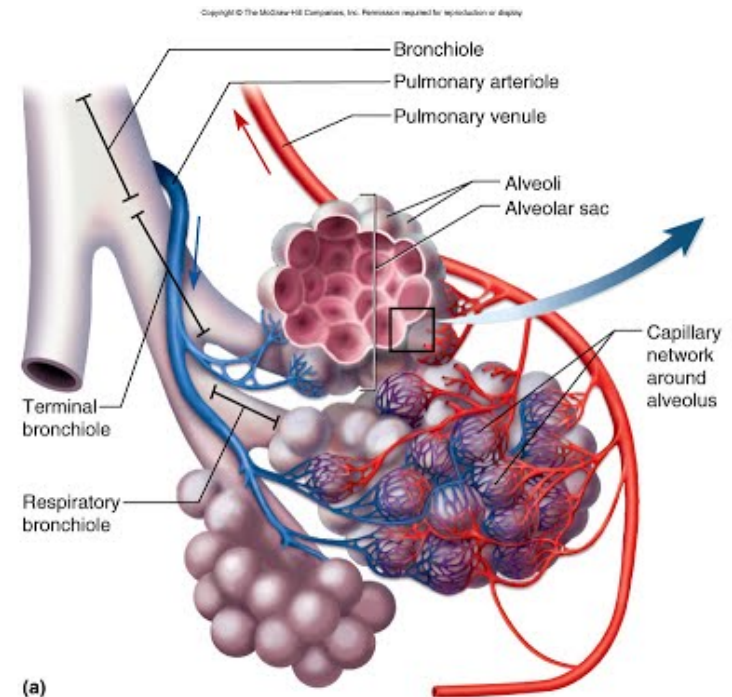

Implications of Viscosity Studies

- ▶ In vascular beds with low shear, particularly those with low oxygen tension (eg., post-capillary venules, bone marrow), any increase in oxygen delivery achieved by transfusion is likely offset by increases in viscosity
- ▶ This would suggest that top-up transfusions are unlikely to be of benefit as treatment for vaso-occlusive crises manifesting as bony pain

Implications of Viscosity Studies

- ▶ In vascular beds with high shear (eg., brain, kidneys, lungs), oxygen delivery may be optimized by increasing the Hct, but with deoxygenated sickle blood there is likely little benefit and possibly harm of transfusing to exceed a Hct of 30%, even if patient's own blood has already been diluted by 75%
- ▶ Moreover, any improvements in oxygen delivery achieved by transfusion in high-shear vascular beds may result in worsened oxygen delivery in low shear beds

Implications of Viscosity Studies: Rules of Thumb

1. In most cases, the benefits of transfusing a patient with sickle cell disease will come from decreasing the viscosity of their blood rather than by increasing its oxygen-carrying capacity
 - ▶ **Goal of transfusion is to decr HgbS%, not incr total Hgb**
 2. Transfusing a patient with sickle cell disease to Hgb > 100-110 g/L may *worsen* their condition, particularly if the patient is already in a hyperviscous state (dehydrated, low-flow, hypoxic)
 - ▶ **Target HgbS% may only be safely achievable by removing patient's own blood prior to transfusing = EXCHANGE TRANSFUSION**
-
- 

Exchange Transfusions

- ▶ “All hospitals that are likely to admit sickle cell disease patients should have staff trained in manual exchange procedures and clearly identified manual exchange procedures, as this can be lifesaving in emergency situations (Grade I C)”
- ▶ “Large referral centres managing patients with sickle cell disease should have facilities and trained staff for automated exchange transfusion (Grade I C).”

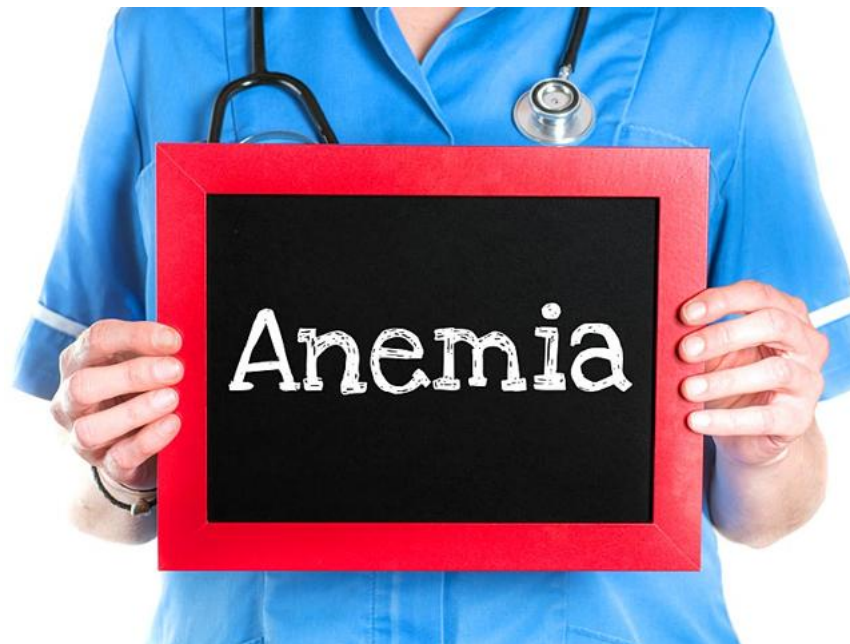

Exchange Transfusions

- ▶ **Manual exchange: No special equipment required, but slow**
 1. Phlebotomize 500 cc
 2. Infuse 500 cc saline
 3. Phlebotomize another 500 cc
 4. Transfuse 2 units RBCs
 5. Repeat as necessary (alternative 1 and 2 units for step 4 if starting Hgb near 100 g/L)

- ▶ **Automated erythrocytapheresis: Specialized equipment/personnel, but fast**
 - ▶ Blood volume estimated based on patient height, weight and Hct
 - ▶ Approximately 150 cc autologous RBCs removed with each cycle and replaced with either saline or homologous RBCs, depending on patient baseline status and goals of therapy

Transfusing to Increase the Oxygen Carrying Capacity

Transfusing for CaO₂

- ▶ Remember: O₂ dissociation curve is *right-shifted* in sickle cell: what seem like symptoms of anemia may in fact reflect medication effects (eg., fatigue), hypovolemia (eg., tachycardia, hypotension), or other disease (eg., dyspnea)
- ▶ Prophylactic transfusions to prevent complications of anemia in sickle cell disease not advised unless Hgb < 50 g/L!

bjh guideline

Guidelines on red cell transfusion in sickle cell disease Part II: indications for transfusion

“Transfusion is not recommended in uncomplicated painful crises but should be considered if there is a substantial drop in Hb from baseline (e.g. >20 g/l or to Hb <50 g/l), haemodynamic compromise or concern about impending critical organ complications (Grade 1C).”

Is there ever a need to increase CaO_2 ?

- ▶ After excluding hemorrhage and hemodilution, there are three major causes of acute anemia exacerbations in sickle cell disease (Hgb decr > 20 g/L from baseline):
 - ▶ Aplastic crisis
 - ▶ Sequestration crisis
 - ▶ Hyperhemolysis

Aplastic crisis

- ▶ Most commonly due to erythrovirus (parvovirus B19)
- ▶ Erythematous rash and arthropathy x 2-3d, then severe reticulocytopenia ($< 50 \times 10^9/L$)
- ▶ Reticulocytopenia lasts 1 week and then recovers as virus cleared by neutralizing antibodies
 - ▶ Lifelong immunity following infection (~75% by age 20)
- ▶ As patients with sickle cell disease have RBC lifespan of only 16-20d, severe anemia may occur during interim (Hgb decr > 30 g/L)

Aplastic crisis

- ▶ As fall in hemoglobin occurs over days, plasma volume has time to increase in compensation
- ▶ Further transfusions therefore risk volume overload; administer slowly and consider prophylactic diuretics
- ▶ For patients with humoral immunodeficiency IVIG 0.5 mg/kg weekly x 4 is reasonable
- ▶ Most patients with SCD have self-limiting disease

Splenic Sequestration Crisis

- ▶ Trapping of sickle erythrocytes in sinusoids results in massive enlargement of spleen (abd pain and distension) and severe anemia over a period of hours, accompanied by reticulocytosis
 - ▶ Often accompanied by thrombocytopenia
- ▶ If untreated, can cause death from hypovolemic shock/anemia
 - ▶ Hepatic sequestration rarer and less severe (liver not as distensible)
- ▶ ~25% incidence in pts with sickle cell disease, most common first 2 years of life, very rare after puberty
- ▶ Chronic transfusions appear to decrease the risk of recurrence, which otherwise occurs in 50% of patients, although mortality rate decreases over time
 - ▶ Goal of transfusion is to buy time for splenectomy

Splenic Sequestration Crisis

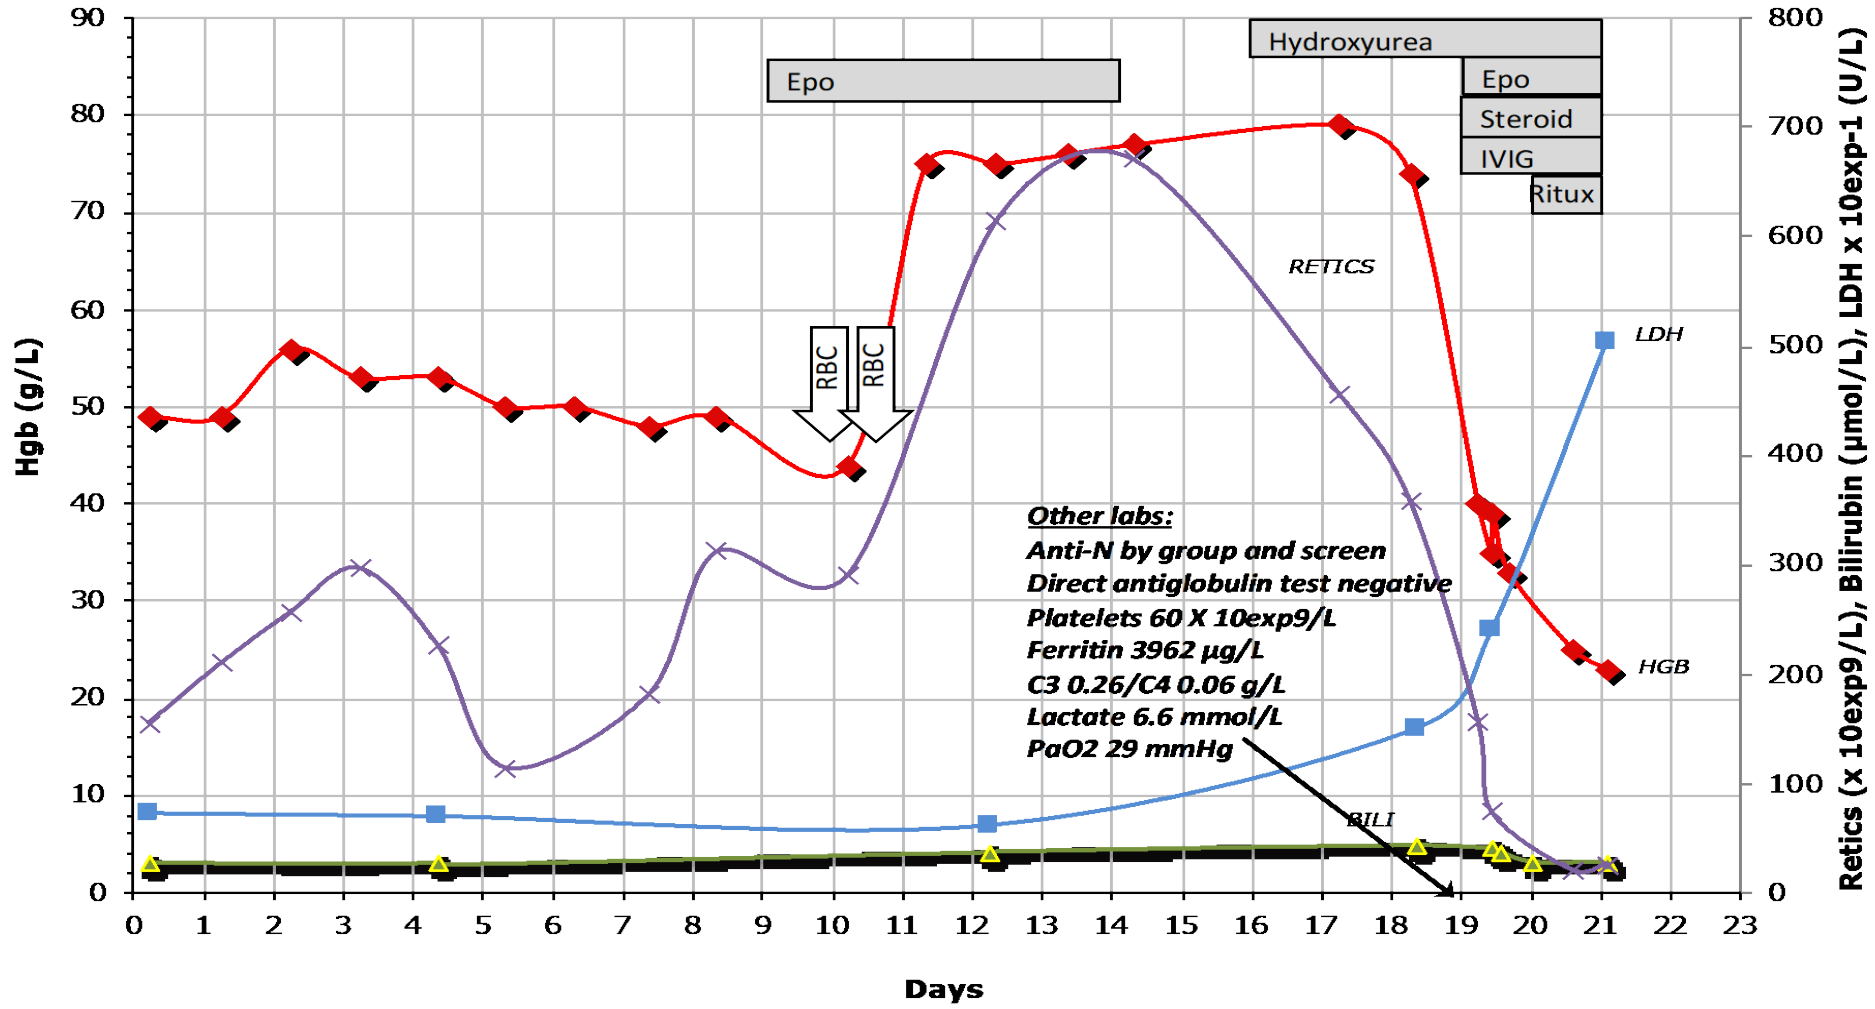

- ▶ Post-transfusion hemoglobin levels often higher than expected, suggesting *autotransfusion*: sequestered RBCs released back into circulation
- ▶ Care must therefore be taken not to accidentally induce polycythemia with attendant risks of hyperviscosity; in children, advisable to administer transfusions in smaller than normal aliquots (eg., 3-5 mL/kg)
- ▶ Often a single transfusion is sufficient to reverse a sequestration crisis

Hyperhemolysis

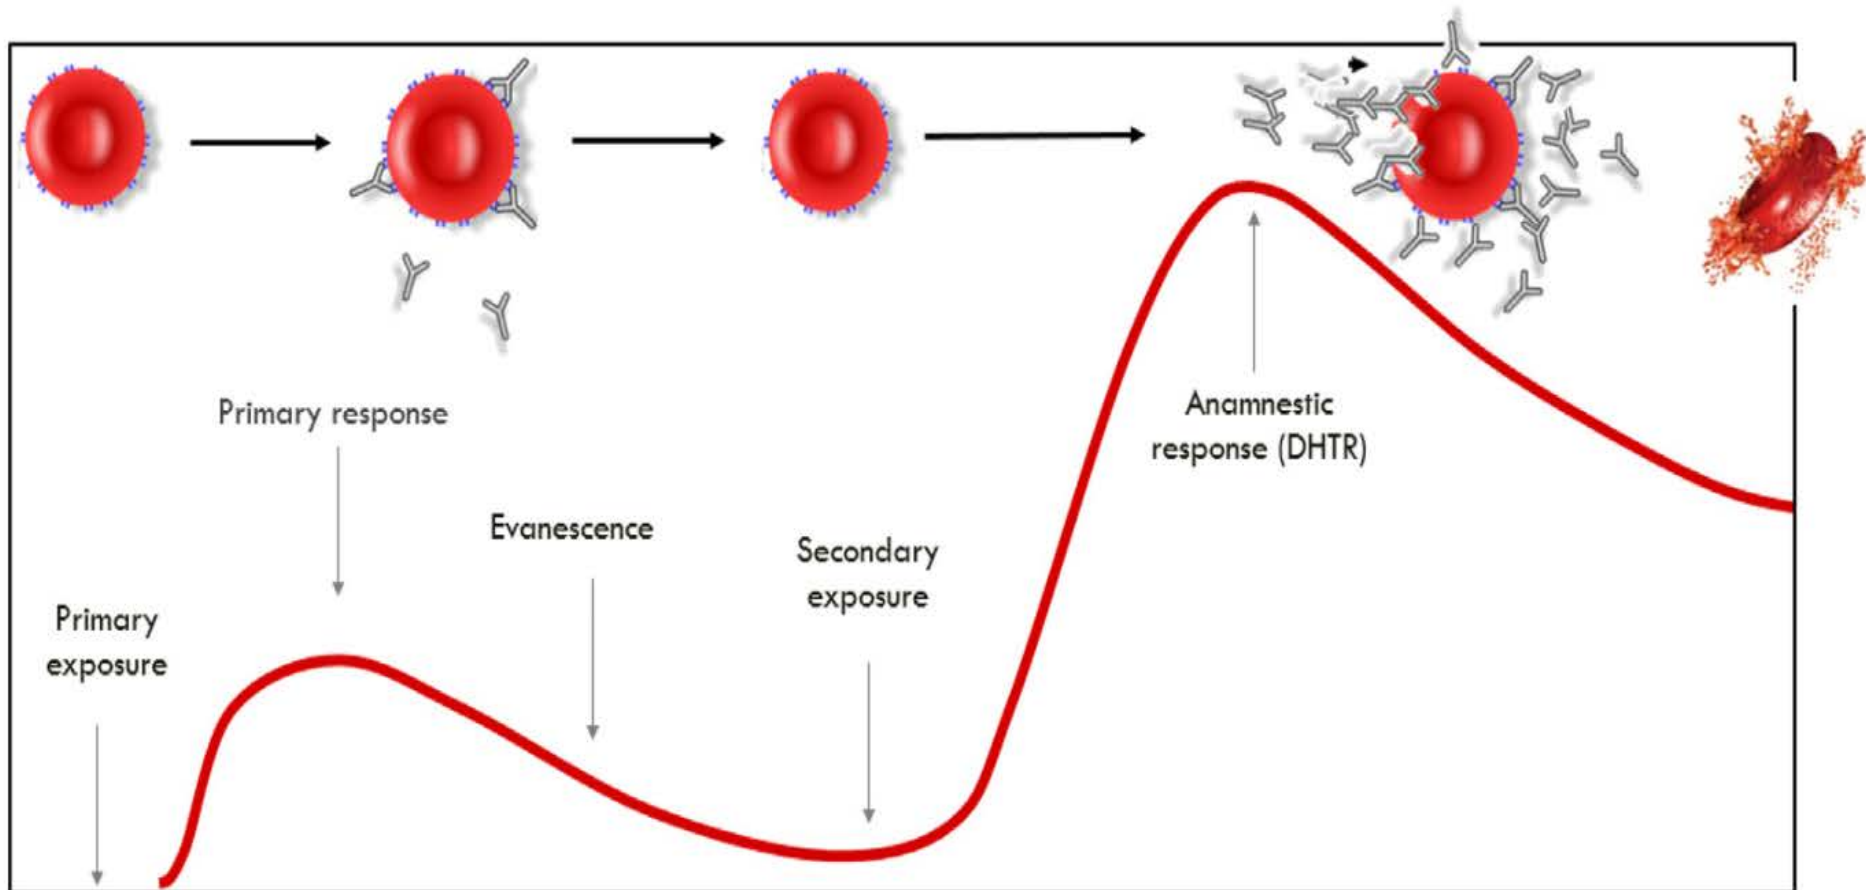

- ▶ Defined as a rapid hemoglobin decline to below pretransfusion level, accompanied by rapid decline of posttransfusion HbA%
- ▶ Cases may initially present as fever and pain, with fall in hemoglobin occurring shortly after
- ▶ Two types
 - ▶ Acute (<7 days post-transfusion): often no evidence of new antibodies
 - ▶ Delayed (>7 days post-transfusion): new antibodies often detected in serum or eluate

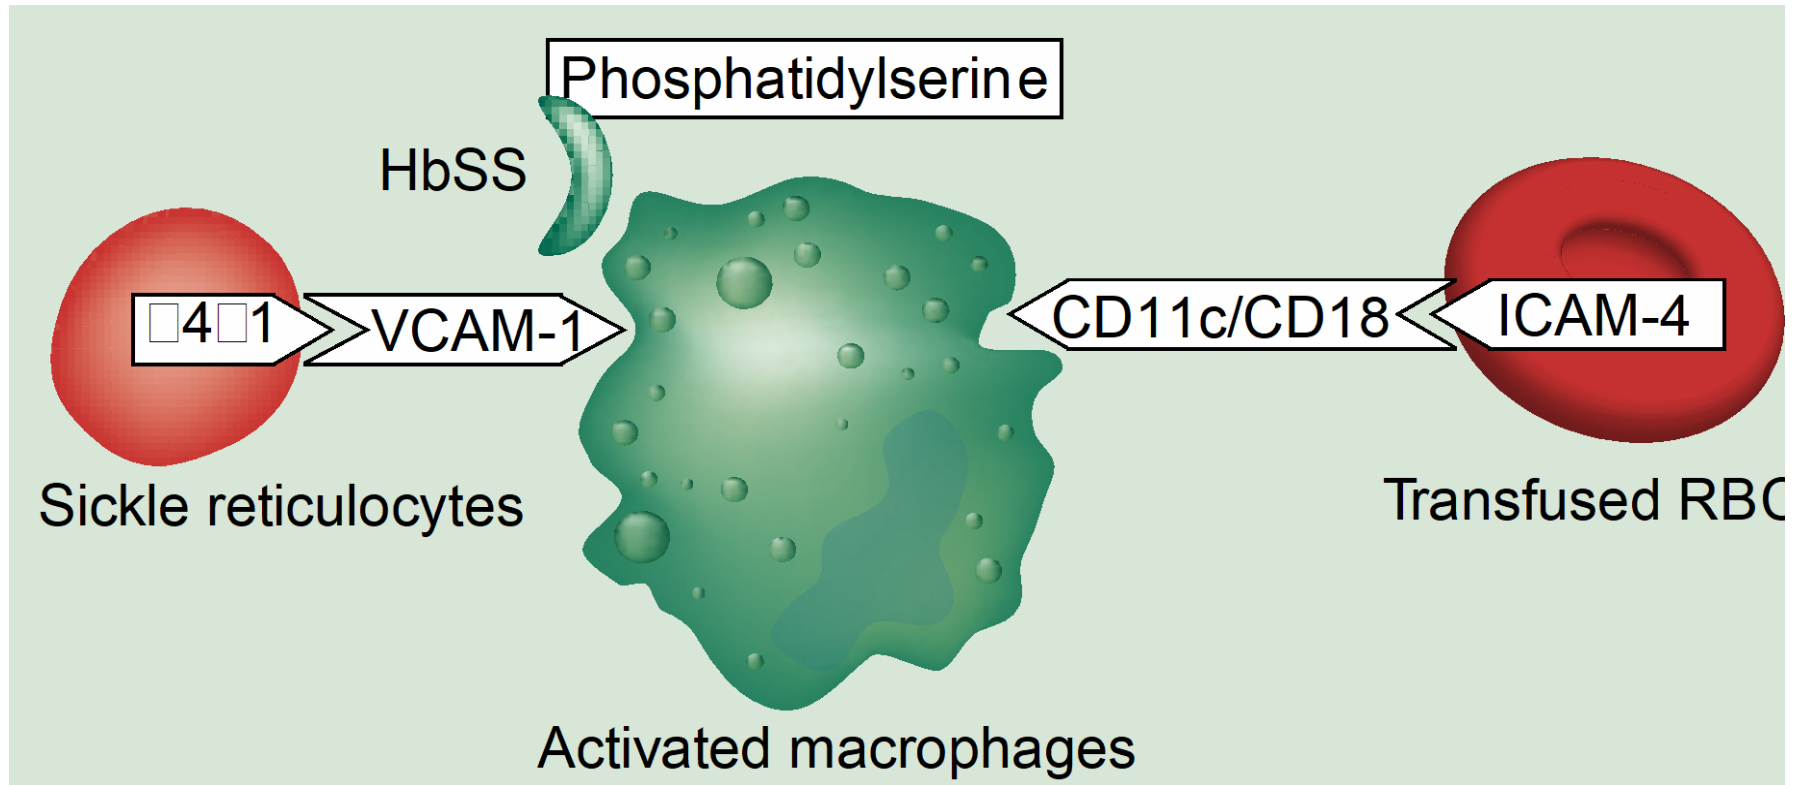

Hyperhemolysis

Traditional Model of Delayed Hemolytic Transfusion Reaction

Hyperhemolysis

Proposed Non-Serologic Mechanisms of Hemolysis

Hyperhemolysis

- ▶ Once diagnosis made, immediately initiate treatment with immunosuppressive therapy
 - ▶ First line: IVIG (2 g/kg over 2-5 days) and high-dose steroids (eg., prednisone 1 mg/kg/day)
 - ▶ Add Epo if reticulocytopenia
- ▶ In cases accompanied by acute organ failure, or if first line therapy has failed, some have advocated
 - ▶ Eculizumab (to interrupt complement-mediated lysis)
 - ▶ Rituximab (to prevent further antibody formation if rescue transfusion required)
- ▶ Once diagnosed, hyperhemolysis is a relative contraindication to all future transfusions

Transfusing to Decrease Whole Blood Viscosity

Transfusing to Decr HgbS%

- ▶ Traditional goal of therapy is to decr HgbS to $< 30\%$ while keeping total Hgb < 110 g/L
 - ▶ In patients with HgbSC, preferable to state goal as HgbA $> 70\%$
- ▶ Available RCT evidence limited to ability of transfusion to **prevent** complications in variety of high-risk settings:
 - ▶ Pregnancy
 - ▶ Perioperative
 - ▶ Stroke prevention
- ▶ Guidelines for **treatment** of complications based largely on observational studies and case series
 - ▶ Acute chest syndrome
 - ▶ Sickle hepatopathy

Transfusing to Decrease Whole Blood Viscosity

Pregnancy

- ▶ Single RCT performed 30+ years ago concluded that initiating a chronic transfusion program for a pregnant HgbSS patient will:
 - ▶ Have no effect on fetal outcomes
 - ▶ Decrease incidence of sickle complications in the mother
- ▶ However, many caveats:
 - ▶ Underpowered (only 36 patients each arm)
 - ▶ Sickest patients excluded (eg., chronic disease of brain, kidney, liver, lung, or coagulation)
 - ▶ Transfusions started relatively late in first trimester (ie., too late to prevent placental insufficiency)
 - ▶ Incidence of neonatal abstinence syndrome not reported

Pregnancy

- ▶ Current guidelines discourage *routine* provision of transfusion support to pregnant women, but still support it for those with:
 - ▶ History of severe SCD-related complications before current pregnancy (including during previous pregnancies)
 - ▶ Additional features of high-risk pregnancy (eg, multiple pregnancy, nephropathy, other comorbidities)

Perioperative

- ▶ Landmark 1995 RCT showed no difference in perioperative outcomes between HgbSS patients randomized to
 - ▶ “Conservative” transfusion: Hgb maintained at 90-110 g/L
 - ▶ “Aggressive” transfusion: HgbS maintained at < 30% and total Hgb 90-100 g/L
- ▶ However, even though all procedures were low-moderate risk, and all patients received careful supportive care, post-operative complications still occurred in both arms
 - ▶ 10% risk of acute chest syndrome, 11% of which required intubation, typically on post-op day 3

Perioperative

- ▶ **TAPS** Trial: Patients with HgbSS/Sβ^o undergoing low-moderate risk surgery randomized to two different perioperative transfusion strategies
 - ▶ 33 pts to supportive care only (no transfusion)
 - ▶ 34 pts to pre-op transfusion within 10d of procedure: top-up if Hgb < 90 g/L, partial exchange if Hgb > 90 g/L (goal of HgbS < 60%)
- ▶ 81% mod risk (eg., cholecystectomy, joint replacement), 19% low risk (eg., adenoidectomy, inguinal hernia repair)

Perioperative

- ▶ Trial stopped early due to increased rate of serious adverse events in untransfused arm (33% vs 3%)
 - ▶ Most significantly acute chest syndrome: 9/33 in untransfused, 1/34 in transfused
 - ▶ Only 1 patient developed acute chest syndrome after low-risk surgery
- ▶ Median time to post-operative complications = 2.5 d
- ▶ Of patients in untransfused arm, 12% were transfused intraoperatively anyway, another 27% post-operatively (most for sickle complications, e.g. ACS)

Perioperative

- ▶ Surgeries without pre-op transfusion complicated by post-operative acute chest syndrome (9 of 33 patients)
 - ▶ Adenoido-tonsillectomy (3)
 - ▶ Laparoscopic cholecystectomy (2)
 - ▶ Tonsillectomy (1)
 - ▶ Laparoscopic splenectomy (1)
 - ▶ Umbilical hernia repair (1)
 - ▶ Shoulder arthroplasty and subacromion decompression (1)
- ▶ A 10th patient developed intra-operative bleeding requiring conversion of laparoscopic to open cholecystectomy, followed by acute chest syndrome
- ▶ 2/10 patients required ICU admission

Perioperative: General Guidelines

Risk	Example	Pre-op transfusion
Low	<ul style="list-style-type: none">• Skin, eyes, nose, ears, dental• Distal extremities• Perineal, and inguinal areas	Not required
Intermediate	<ul style="list-style-type: none">• Abdominal or orthopedic procedures• Oropharyngeal procedures	Top-up transfusion to 100 g/L (approx HgbS 60%); exchange if Hgb > 90g /L
High	<ul style="list-style-type: none">• Intracranial, cardiovascular, or intrathoracic procedures• Scleral buckling• Intermediate-risk procedures in patients with significant comorbidities (eg., chronic pulmonary disease), or with baseline Hgb > 90g/L	Exchange transfusion to HgbS of 30% (HgbA 70%)

Stroke prevention

- ▶ RCTs in children with SSD have shown that
 - ▶ Transfusion remains first line therapy for both primary and secondary stroke prevention
 - ▶ In patients being transfused for *secondary* prophylaxis, must maintain HgbS% of <30% indefinitely (and continue monitoring: may not be sufficient to completely prevent progressive disease)
 - ▶ In patients being transfused for *primary* prophylaxis, careful transition to hydroxyurea after > 1 year of transfusion may be feasible
 - ▶ For patients with silent infarcts (25-35% prevalence!), transfusion decisions should be made case-by-case

Adams, NEJM. 1998;339:5

Adams, NEJM. 2005;353:2769

Ware, Blood. 2012;119:3925

DeBaun, NEJM. 2014;371:699

Ware, Lancet. 2016;13:387

Stroke prevention

- ▶ In adults with sickle cell disease, very little evidence to base practice on
- ▶ If no obvious other explanation (eg., vasculopathy apparent on angiogram and no evidence of cardioembolism) usual practice is to initiate chronic transfusion support following new onset symptomatic stroke
 - ▶ In presence of *hemorrhagic* stroke, may be prudent to wait until bleeding has stopped

Prevention of recurrent crises

- ▶ While benefit of chronic transfusion in preventing pain crises not directly assessed in RCTs, it is a consistent observation in subgroup analyses of other studies (pregnancy, perioperative care, stroke prevention), and is more effective than hydroxyurea
- ▶ Reasonable to consider trial of chronic transfusion in patients with recurring and severe pain crises who:
 - ▶ Have not benefited from, or cannot safely take, high-dose hydroxurea
 - ▶ Do not have a chronic pain syndrome (eg., AVN, opioid-induced hyperalgesia etc)
- ▶ Similar approach reasonable to prevent recurrent ACS or priapism

Transfusing to Decrease Whole Blood Viscosity

Acute Chest Syndrome

- ▶ Standard definition encompasses a broad range of disease severity: *new pulmonary infiltrate on CXR accompanied by fever and/or resp symptoms*
- ▶ May be triggered by infection or marrow embolism; specific cause not identified in ~60% of cases despite extensive investigations

www.radiology.vcu.edu

Acute Chest Syndrome

- ▶ Largest observational study of 671 episodes noted¹
 - ▶ 72% of pts received transfusions, ~2/3 of them top-up transfusions
 - ▶ Transfusion associated with improvement in gas exchange (PO₂ 68 →71 mmHg and SpO₂% 91% →94%)
 - ▶ Simple and exchange transfusions resulted in “similar” improvements (data not shown)
- ▶ However, an earlier case series reported that 40% of patients referred for exchange transfusion for ACS had failed earlier attempt at top-up transfusion.²

1. Vichsinky, NEJM 2000;342:1855

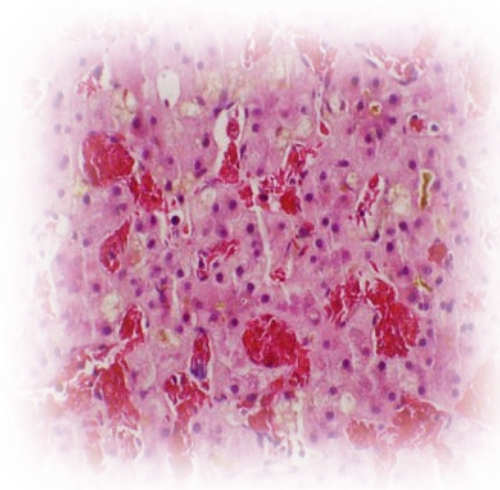

2. Wayne, Blood 1993;181:1109

Acute Chest Syndrome

- ▶ In absence of RCT evidence, guidelines recommend transfusions for all but mildest cases, and exchange transfusions for patients with poor prognostic markers
- ▶ Physical exam
 - ▶ Altered mental status
 - ▶ Persistent HR > 125/min
 - ▶ Persistent RR > 30 or other evidence of incr work of breathing
 - ▶ Temp > 40C
 - ▶ Hypotension vs baseline
- ▶ Lab/radiologic findings
 - ▶ Arterial pH < 7.35
 - ▶ SpO2 persistently < 88% despite aggressive ventilatory support
 - ▶ Serial decline in SpO2% or A-a gradient
 - ▶ Hgb decr by ≥ 20 g/L
 - ▶ Plts < 200/fL
 - ▶ Elevated BNP or troponin
 - ▶ Evidence of multiorgan failure
 - ▶ Pleural effusion
 - ▶ Progressive pulm infiltrates

Other Indications for Therapeutic Transfusion

- ▶ **Sickle cell intrahepatic cholestasis (sickle hepatopathy)**
 - ▶ Severe RUQ pain, acute hepatomegaly, coagulopathy, extreme hyperbilirubinemia (predominantly conjugated), only moderately elevated liver enzymes
 - ▶ Occasionally progresses to acute liver failure
 - ▶ Chronic (benign) form more common in children; in adults may progress to severe liver dysfunction requiring transplant
 - ▶ Acute forms (accompanied by sequestration) may occur in setting of VOC and be precipitated by intercurrent infection or exposure to hepatotoxin: **DO NOT BIOPSY**
 - ▶ Case reports of improvement from exchange transfusion

Other Indications for Therapeutic Transfusion

- ▶ In absence of good evidence, many advocate transfusion for specific complications only if standard-of-care, non-transfusion approaches have failed:
 - ▶ *Priapism*: voiding, hydration, analgesics, heat, vasodilators, aspiration/irrigation, adrenergic agents. Beware of ASPEN syndrome (Association of SCD, Priapism, Exchange transfusion, and Neurologic events)
 - ▶ *Malleolar ulcers*: wound care, antibiotics, compression stockings
 - ▶ *Proliferative retinopathy*: phototherapy, cryotherapy, vitrectomy, scleral buckling
 - ▶ *Avascular necrosis*: physiotherapy
 - ▶ *Renal dysfunction*: ACE-I
 - ▶ *Pulmonary hypertension*: vasodilators (confirm pre-capillary cause)
- ▶ Hydroxyurea and/or phlebotomy should also be considered for the above and may be safer than transfusion

“What’s the takeaway on all this?”

Overview of Transfusion Indications for SSD

Generally Accepted	Possibly Effective	Not Indicated
<ul style="list-style-type: none"> • Acute cerebrovascular accident • Primary and secondary stroke prevention • Retinal artery occlusion • Acute and recurrent splenic sequestration • Intrahepatic cholestasis • Acute chest syndrome • Aplastic crisis • Pre-operative for moderate to high-risk procedure • Hemorrhage (eg., splenic rupture) • Prevention of pain crises 	<ul style="list-style-type: none"> • Recurrent or persistent priapism • Pulmonary hypertension • Progressive renal failure • Pregnancy with exacerbation of anemia or evidence of placental insufficiency • Severe sepsis 	<ul style="list-style-type: none"> • Compensated anemia • Infections other than aplastic crisis or acute chest syndrome • Treatment of uncomplicated pain crisis • Pre-operative for minor procedures • Non-surgical management of avascular necrosis • Uncomplicated pregnancy

HEMATOLOGY CONSULTATION

With regard to transfusion of patients with sickle cell disease, which is true?

Unlike patients transfused for thalassemia, SCD patients are not at risk of developing iron overload

Transfusion triggers are the same for patients with and without sickle cell disease

Delayed haemolytic transfusion reactions are common unless phenotypically matched blood is provided

Units for transfusion should be irradiated

Alloantibody development occurs rarely in the transfused SCD patient.

Selection of RBCs

Prevention of Alloimmunization

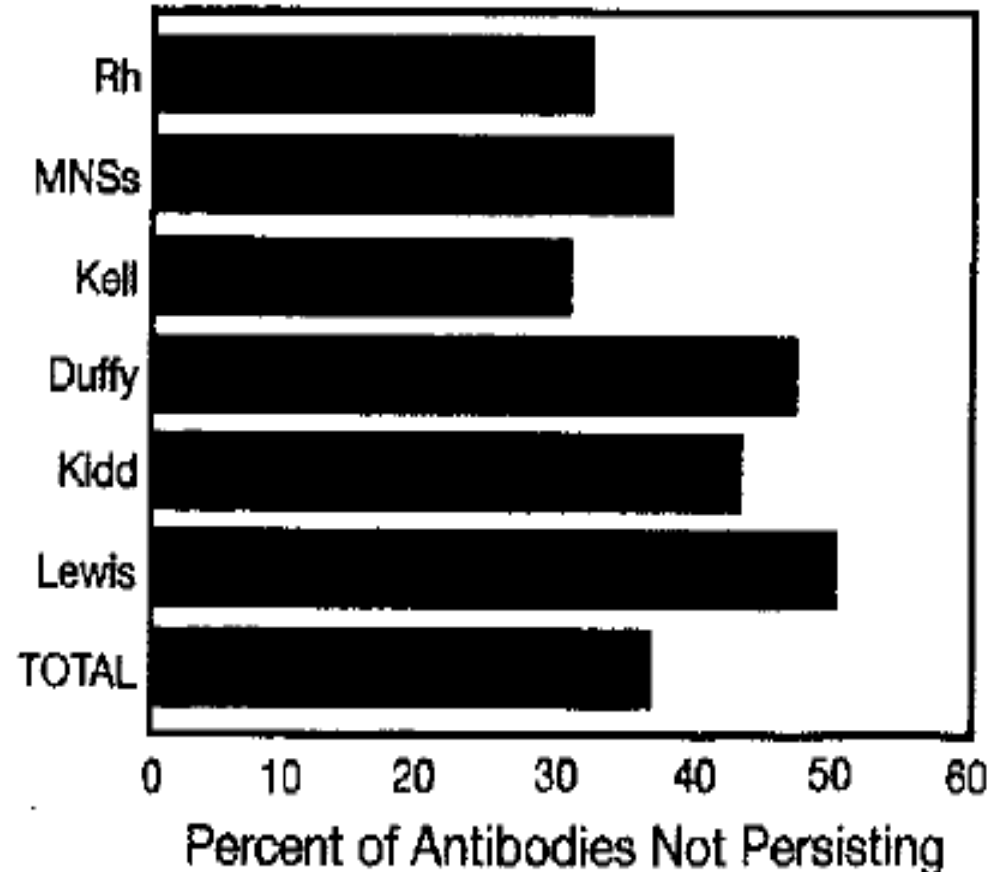

- ▶ Approx 25% of patients with SSD will become alloimmunized from transfusion
- ▶ Traditionally assumed to represent differences in antigen expression between typical donor and sickle cell patient

Table 3. Average Frequencies of RBC Alloantibodies Made By Transfused Patients With SCD

Antibody	Average frequency (%)
Anti-E	21
Anti-K	18
Anti-C	14
Anti-Le ^a	8
Anti-Fy ^a	7
Anti-Jk ^b	7
Anti-D	7
Anti-Le ^b	7
Anti-S	6
Anti-Fy ^b	5
Anti-M	4
Anti-E	2
Anti-C	2

Detection of Alloantibodies

- ▶ In patients with sickle cell disease, 30-50% of antibodies will be detectable on at least one occasion 1 year after they were first observed
- ▶ Episodic transfusions in different hospitals increases risk of DHTRs and possibly hyperhemolysis
- ▶ **Note, though, that many DHTRs in sickle cell will not be accompanied by evidence of serologic incompatibility**

Reasons for Failure of Prophylactic Matching

- ▶ Laboratory/transcription error in phenotype of either donor or recipient
- ▶ Failure to notify blood transfusion service of patient diagnosis
- ▶ Inability to source antigen-typed units for urgent transfusion
- ▶ Genotype/phenotype discrepancy (eg., partial Rh antigens)

Other Considerations

- ▶ Transfusion of HgbS-containing units (eg, from sickle trait donors) may confound attempts to monitor response to transfusion but does not itself pose any significant harm to patients
- ▶ Transfusion of fresh RBCs (eg., < 7-10 days) may prolong interval between transfusions but is not mandatory
- ▶ ***The above considerations are of much lesser importance than the provision of antigen-typed units***
- ▶ Genotyping of donors allows for more careful selection of RBCs than traditional phenotyping and should be performed in all patients

Other Considerations

- ▶ Improved transfusion support of sickle cell patients still comes primarily from “low-tech” solutions:
 - ▶ Judicious ordering of blood products by clinicians (eg., not for asymptomatic anemia or uncomplicated pain crisis)
 - ▶ Incr recruitment of donors from ethnic minority groups
 - ▶ Better communication between clinicians and laboratory regarding patient diagnosis
 - ▶ Better communication between hospital blood transfusion services regarding patient phenotype and antibody history (tell your blood bank if your patient has ever been transfused elsewhere)
- ▶ **Safest option? Get a hematology consult before you operate on or transfuse a patient with sickle cell disease**

QUESTIONS/COMMENTS?

▶ PRINCIPLES

- ▶ Decr HgbS%, generally more important than increasing total Hgb
- ▶ Benefit only with high-shear vasculature
- ▶ Ceiling of Hgb ~100 g/L

▶ CAUTION WITH SEVERE ANEMIA

- ▶ Aplastic crisis: *volume overload*
- ▶ Sequestration: *autotransfusion*
- ▶ Hyperhemolysis: *worsening anemia*

▶ NUANCED APPROACH FOR SURGERY

- ▶ Usually not needed for low-risk patient with low risk procedure
- ▶ Indicated for everyone else, top-up vs exchange depends on comorbidity, procedure risk, baseline hemoglobin

▶ WEAK EVIDENCE WITH PREGNANCY

- ▶ Available evidence suggests more benefit for mom than developing fetus
- ▶ There may be exceptions (eg., signs of placental insufficiency, prev IUGR)

▶ GOOD EVIDENCE FOR STROKE PREVENTION

- ▶ Transfusion indicated for all children with high-risk dopplers and history of stroke
- ▶ Smaller value for children with SCIs
- ▶ Limited evidence in adults; look for other causes, caution with hemorrhagic stroke

▶ THERAPEUTIC TRANSFUSION IF ACUTE ORGAN COMPROMISE

- ▶ Limited evidence, but consensus supports transfusion for acute stroke, acute chest syndrome, sickle hepatopathy
- ▶ Other situations: “if all else fails”

▶ SELECTION OF RBCs MUST BE DONE WITH CARE!

- ▶ Tell your blood bank early that your patient has sickle cell, provide detailed transfusion history
